SVM and Kernels

Problem 1:

Similarities:

Both try to find a fitting hyperplane which separates the data classes.

Difference:

SVM tries to maximize the margin from the hyperplane to the data points, perceptron algorithms only care about a valid separation of the data classes.

Problem 2:

a)

$g(\alpha)$ vectorized definition:

$$g(\alpha) = \frac{1}{2} \alpha^T Q \alpha + \alpha^T \mathbf{1}_N$$

$g(\alpha)$ standard definition:

$$g(\alpha) = \sum_{i=1}^N \alpha_i - \frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N y_i y_j \alpha_i \alpha_j x_i^T x_j$$

y is a vector of dimension $N \times 1$

x is a matrix of dimension $N \times M$

$\sum_{i=1}^N \sum_{j=1}^N y_i y_j$ is equivalent to yy^T (dimension is $N \times N$)

$\sum_{i=1}^N \sum_{j=1}^N x_i^T x_j$ is equivalent to XX^T (dimension is $N \times N$)

$\sum_{i=1}^N \sum_{j=1}^N y_i y_j x_i^T x_j$ is the Hadamard product so: $[yy^T \odot XX^T]$

Take the -1 scalar from the standard definition into the matrix: $[-yy^T \odot XX^T] = Q$

$$\implies \frac{1}{2} \alpha^T Q \alpha \equiv \frac{1}{2} \alpha^T [-yy^T \odot XX^T] \alpha \equiv -\frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N y_i y_j \alpha_i \alpha_j x_i^T x_j$$

$\alpha^T \mathbf{1}_N \equiv \sum_{i=1}^N \alpha_i$ is trivial.

$$\implies g(\alpha) \text{ vectorized definition} \equiv g(\alpha) \text{ standard definition}$$

b)

If the search for a local maximizer of g returns the global maximum of g , that means that the maximization problem is concave.

To prove this claim Q needs to be negativ (semi)definite (NSD).

For Q to be NSD: $\forall \alpha \in \mathbb{R}^N : \alpha^T Q \alpha \leq 0$ needs to hold.

$$\alpha^T Q \alpha \leq 0 \quad (1)$$

$$-\sum_{i=1}^N \sum_{j=1}^N y_i y_j \alpha_i \alpha_j x_i^T x_j \leq 0 \quad (2)$$

$$-\sum_{i=1}^N \sum_{j=1}^N (y_i \alpha_i x_i)^T (y_j \alpha_j x_j) \leq 0 \quad (3)$$

$$-(y \odot \alpha)^T X X^T (y \odot \alpha) \leq 0 \quad (4)$$

$$-(y \odot \alpha)^T (X^T)^T X^T (y \odot \alpha) \leq 0 \quad (5)$$

$$-(X^T (y \odot \alpha))^T (X^T (y \odot \alpha)) \leq 0 \quad (6)$$

$$-(X^T (y \odot \alpha))^2 \leq 0 \quad (7)$$

$$-(\geq 0) \leq 0 \quad \square \quad (8)$$

(3): y_i and α_i can be dragged inside here because they are scalars.

(4): The whole expression returns a scalar, that's why reshaping is done this way:

$$\dim((y \odot \alpha)^T) = 1 \times N$$

$$\dim(X) = N \times 1$$

$$\dim(X^T) = 1 \times N$$

$$\dim((y \odot \alpha)) = N \times 1$$

$$(5): X = (X^T)^T$$

$$(6): (AB)^T = B^T A^T$$

$$(7): (\dots)^2 \geq 0, \text{ (as long as } \dots \text{ is not complex)}$$

(8): Proofs that Q is NSD.

Q is NSD, that means the maximization problem is in fact concave so local maxima = global maxima.

Problem 3:

Problem 4:

Problem 5:

"A kernel is valid if it corresponds to an inner product in some feature space."

$x_1^T x_2$ is a valid kernel because it is a scalar product of the input vectors.

a_0 is a constant term and a valid kernel because it can be generated by:

$$k(x_i, x_j) = \phi(x_i)^T \phi(x_j) \text{ with } \phi(x) = \sqrt{a_0} \implies k(x_i, x_j) = a_0$$

The same holds for a_i so $a_i (x_i^T x_j)^i + a_0$ can be represented as kernels.

Sums and multiplications of kernels are kernel preserving (also scalars are ≥ 0)

\implies Gram matrix is still PSD.

Problem 6:
